STATEMENT OF RELATED APPLICATIONS

The present application is a divisional of co-pending application Serial No. 10/429,875, filed May 6, 2003, which is a continuation-in-part of application Serial No. 10/094,301, filed March 8, 2002, now abandoned, the contents of each are herein incorporated by reference in their entirety.

BACKGROUND OF THE INVENTION

The present invention relates to the use of compounds such as amide, carbazide and hydrazide derivatives as selective inhibitors of bacterial pathogens. In particular the invention refers to a family of compounds that block the quorum sensing system of Gram-negative bacteria, a process for their manufacture, pharmaceutical compositions containing them and to their use for the treatment and prevention of microbial damages and diseases, in particular for diseases where there is an advantage in inhibiting quorum sensing regulated phenotypes of pathogens.

Many microorganisms, including bacteria, fungi, protozoa and algae cause severe damages or diseases in different areas such as industry, agriculture, environment and medicine. Especially bacteria as human pathogens cause tremendous costs in public health systems worldwide. The continuing emergence of multiple-drug-resistant bacterial strains has necessitated finding new compounds that can be used in antibacterial treatment. There are two broad strategies for the control of bacterial infection: either to kill the organism or to attenuate its virulence such that it fails to adapt to the host environment. The latter approach has, however, lacked specific targets for rational drug design. The discovery that Gram-negative bacteria employ a signal transduction pathway comprising a small molecule to globally regulate the production of virulence determinants offers such a novel target.

A wide variety of Gram-negative bacteria produce N-acyl-L-homoserine lactone (AHL or HSL, **FIG. 1**) derivatives as signal molecules in intercellular communication. These molecules, also referred to as "pheromones" or "quoromones", comprise a homoserine lactone moiety linked to an acyl side chain. Bacteria use this signaling system to monitor their population cell density in a process referred to as "quorum sensing". In each cell of a population an HSL synthase from usually the LuxI family of proteins

produce a low basal level of diffusible HSLs. The HSL concentration increases with bacterial population density until a threshold concentration is reached which results in expression of various HSL-dependent genes through an HSL-receptor protein belonging generally to the LuxR family of transcriptional regulators. This HSL-receptor protein complex serves not only as positive transcription regulator of quorum sensing regulated genes but also as positive regulator for the HSL synthesis itself. Therefore, the entire system is amplified via a process of autoinduction.

This system was first discovered in the bioluminescent marine bacteria *Vibrio harveyi* and *V. fischeri* where it is used to control bioluminescence expression. In recent years it has become apparent that many Gram-negative bacteria employ one or more quorum sensing systems comprising HSL derivatives with different acyl side chains to regulate in a cell-density dependent manner a wide variety of physiological processes such as swarming motility, biofilm formation, pathogenicity, conjugation, bioluminescence or production of pigments and antibiotics (Table 1, for reviews and further references see, e.g.: Fuqua et al, *Ann. Rev. Microbiol.* 50:727-51, 1996; Fuqua & Greenberg, *Curr. Opinion Microbiol.* 1:183-89, 1998; Eberl, *Syst. Appl. Microbiol.* 22:493-506, 1999; De Kievit & Iglewski, *Infect. With regard to bacteria that utilize HSL-based quorum sensing as part of their lifestyle, *Pseudomonas aeruginosa* is perhaps the best understood in terms of the role quorum sensing plays in pathogenicity. In this human opportunistic pathogen, which causes nosocomial infections in immunocompromized patients and has an extremely high potential to develop resistance mechanisms against traditional antibiotic treatment, production of many virulence factors including expression of alkaline protease, endoproteinase, LasA protease, LasB elastase, anthranilate synthase, hemolysins, lectin, cytochrome c oxidase, catalase, Mn- and Fe-dependent superoxide dismutases, exotoxin A, exoenzyme S, chitinase, chitin binding protein, phenazine, hydrogen cyanide, pyocyanin, pyoverdine, phospholipase C, rhamnolipids, sigma factor S, components of the protein secretion apparatus, efflux transporters, production of alginate and adhesion, twitching motility and pilin export is regulated by two interlinked quorum sensing circuits. Moreover, it has been demonstrated that this signaling system is involved in the ability of *P. aeruginosa* to form biofilms (Davies et al, *Science* 280:295-8, 1998). Recently Huber et al. (*Microbiology* 147:2517-28, 2001) demonstrated that biofilm formation and swarming

motility of *Burkholderia cepacia*, like *P. aeruginosa* a human opportunistic pathogen, is also dependent on an HSL-based quorum sensing system.

Biofilms are defined as an association of microorganisms growing attached to a surface and producing a slime layer of extracellular polymers in which the microbial consortia is embedded in a protective environment (for a review see: Costerton et al., *Ann. Rev. Microbiol.* 49:711-45, 1995). Biofilms represent a severe problem as bacteria integrated in such a polymer matrix develop resistance to conventional antimicrobial agents. *P. aeruginosa* cells, for example, growing in an alginate slime matrix have been demonstrated to be resistant to antibiotics (e.g., aminoglycosides, β -lactam antibiotics, fluoroquinolones) and disinfectants (Govan & Deretic, *Microbiol. Rev.* 60:539-74, 1996). Several mechanisms for biofilm-mediated resistance development have been proposed (Costerton et al., *Science* 284:1318-22, 1999).

In most natural, clinical and industrial settings bacteria are predominantly found in biofilms. Drinking water pipes, ship hulls, teeth or medical devices represent typical surfaces colonized by bacteria. On the one hand biofilms decrease the life time of materials through corrosive action in the industrial field, a process also referred to as “biofouling”. Furthermore, microbial biofilms growing for example on ship hulls increase fuel consumption through enhanced frictional resistance and simultaneously reduce maneuverability. On the other hand two thirds of all bacterial infections in humans are associated with biofilms (Lewis, *Antimicrob. Agents Chemother.* 45:999-1007, 2001).

Pseudomonas aeruginosa, for example, forms infectious biofilms on surfaces as diverse as cystic fibrosis lung tissue, contact lenses, and Catheter tubes (Stickler et al., *Appl. Environm. Microbiol.* 64:3486-90, 1998). *Burkholderia cepacia* also forms biofilms in lungs of cystic fibrosis patients and is a major industrial contaminant (Govan et al., *J. Med. Microbiol.* 45:395-407, 1996). Since biofilm formation of both organisms is demonstrated to require an HSL signaling system, inhibition of their quorum sensing systems would result in an impaired ability to form biofilms and therefore in an increased susceptibility to antibacterial treatment.

Beside the role of HSL derivatives as signaling molecules of bacterial cell-to-cell communication it has been demonstrated that HSL interfere also with higher organisms.

Since HSL derivatives inhibit murine and human leucocyte proliferation and TNF-alpha secretion by lipopolysaccharide (LPS) stimulated human leucocytes (Chhabra et al., *J. Med. Chem.* 46:97-104, 2003), the suitability of these compounds for immunological diseases, particularly autoimmune diseases such as psoriasis, rheumatoid arthritis, multiple sclerosis and type 1 (autoimmune) diabetes is indicated (WO 03/004017, WO 03/022828).

Furthermore, certain HSL molecules are capable of reducing the heart beat without substantially reducing arterial blood pressure. These compounds and analogs of them could, therefore, be suitable for the treatment of cardiac tachyarrhythmias, ischaemic heart disease, congestive heart failure (WO 01/26650). Additionally, HSL compounds have been reported as possible antiallergic drug (WO 95/01175) and for the treatment of a range of diseases including cancer, breast cancer, obesity, lipid metabolism disorders, immune disease, immune deficiency or immune disorders by modulationg STAT activity (WO 03/026641).

The discovery that a wide spectrum of bacterial organisms use quorum sensing to control virulence factor production and other phenotypes such as biofilm formation makes it an attractive target for antimicrobial therapy. Pathogenic organisms using this signaling system to control virulence could potentially be rendered avirulent by blocking this cell-cell communication system. In contrast to traditional antibiotics, the risk of resistance development seems to be very low, since quorum sensing blocking agents would not kill the organism but disturb signal transduction pathways. There are several possibilities of interrupting the quorum sensing circuit.

For example, plants expressing an HSL-lactonase enzyme originally derived from *Bacillus* sp. have been demonstrated to quench pathogen quorum sensing signaling and to significantly enhance resistance to *Erwinia carotovora* infections (Dong et al., *Nature* 411:813-7, 2001). An alternative way to block cell signaling could be to interrupt the HSL synthesis by using analogs of HSL precursors.

However, the most promising possibility to block quorum sensing is to take advantage of the unique specificity the HSLs and HSL-receptor proteins show for one another. The ability of homoserine lactone-based analogs to inhibit activation of HSL-receptor proteins has already been demonstrated in a number of bacteria including *Vibrio*

fischeri (Schaefer et al, *J. Bacteriol.* 178:2897-901, 1996), *Agrobacterium tumefaciens* (Zhu et al., *J. Bacteriol.* 180:5398-405, 1998), *Chromobacterium violaceum* (McLean et al., *Microbiology* 143:3703-11, 1997), *Aeromonas salmonicida* (Swift et al., *J. Bacteriol.* 179:5271-81, 1997) and *Pseudomonas aeruginosa* (Pesci et al., *J. Bacteriol.* 179:3127-32, 1997). However, none of these compounds have been developed as antimicrobial agents, e.g. in medical therapy, so far.

There are only a few non-HSL-based antimicrobials described which are supposed to interfere specifically with HSL-regulated processes, for example halogenated furanone derivatives which are structurally similar to HSLs and have been isolated from red marine algae *Delisea pulchra* (WO 96129392; Hentzer et al., *Microbiology* 148:87-102, 2002). Additionally, these substances have been demonstrated to inhibit also Gram-positive bacteria (WO 99/53915). However, the use of most of these furanone compounds is limited due to their toxicity making them unsuitable for veterinary and medical applications.

Furthermore, Smith et al. (*Chem. Biol.*, 10:81-9, 2003) recently published *Pseudomonas aeruginosa* HSL analogs with slight structural variations targeted to the HSL moiety which act both as quorum sensing agonists and antagonists. Additionally, WO 02/088298 reportedly provides certain nitrogen heterocyclic molecules for controlling biofilms based on the interference with quorum sensing.

Many target genes involved in biofilm formation, methods of screening for compounds to control biofilm development and HSL-based compositions to prevent biofilm formation have been described (WO 99/55368, WO 98/57618, WO 99/27786, WO 98/58075), but until now no promising antibacterial drug candidate has been developed that is capable of inhibiting virulence gene expression and biofilm formation in different areas, preferentially in the medical field.

It is an object of the present invention to provide compounds blocking specifically quorum sensing regulated processes without inhibiting bacterial growth. Furthermore, these compounds should not be structural derivatives of the homoserine lactone family of regulatory compounds and should not exhibit any toxic properties.

BRIEF SUMMARY OF THE INVENTION

Accordingly, we have been able to find compounds that can significantly reduce virulence gene expression and biofilm formation of several human pathogens. In contrast to the furanones the compounds of this invention do not show any toxic effect and are therefore suitable for applications in a wide area. Such applications could be the use of the compounds for instance as new antibiotic therapeutics, disinfectants, antifouling coatings or coatings of medical devices. In contrast to traditional antibacterial agents (like amide or 1,2-acylhydrazine derivatives in WO 01/51456; for the synthesis of amide or 1,2-acylhydrazine derivatives see also EP 638545 and EP 982292), the compounds of the present invention do not kill the microorganisms, but render them avirulent. The advantage of this alternative strategy is that the emergence of bacterial resistance against such antimicrobials is extremely improbable.

In general, the present invention provides compounds selectively modulating bacterial cell-cell communication. Through inhibition of this communication system the expression of many HSL-dependent virulence genes and other phenotypes like swarming motility and biofilm formation are significantly reduced or completely abolished rendering a bacterial population more susceptible to the host immune-response or to treatment with traditional antibacterial agents.

Thus, in one aspect, the invention refers to a method for inhibiting an HSL-regulated process in a microorganism by exposing the microorganism to a new class of compounds with an inhibitory effect on bacterial signaling.

The compounds of the Formula (XIII), (I), (X), (XI) or (XII) according to the invention can be also used in form of the corresponding salts with inorganic or organic acids or bases. Examples of such salts are, e.g., alkali metal salts, in particular sodium and potassium salts, hydrochloride or ammonium salts.

In general, the compounds of the present invention can be used to inhibit quorum sensing signaling of bacteria employing HSLs as signal molecules for cell-cell communication. Preferably, the compounds can be applied to the bacteria listed in Table 1, and more preferably to the bacteria of Table 1 that are pathogens. In the following it is explained that the compounds of the present invention can be used as antibacterial agents in various applications.

In a preferred form, the compounds of Formula (XIII), (I), (X), (XI) or (XII) are useful for the treatment of a variety of human, animal and plant diseases, where bacterial pathogens regulate the expression of virulence genes and other phenotypes, e.g. biofilm formation,

through an HSL-based quorum sensing system. Furthermore, as the list of organisms (see Table 1) employing quorum sensing signaling for their virulence continues to increase, the compounds of the invention can be used also for organisms which will be added to the above listed in future.

In a first embodiment, the compounds are useful for the treatment of mammalian in particular human diseases caused by bacteria through the inhibition of the bacterial quorum sensing cascade rendering the pathogen avirulent. Such diseases include endocarditis, respiratory and pulmonary infections (preferably in immunocompromized and cystic fibrosis patients), bacteremia, central nervous system infections, ear infections including external otitis, eye infections, bone and joint infections, urinary tract infections, gastrointestinal infections and skin and soft tissue infections including wound infections, pyoderma and dermatitis which all can be triggered by *Pseudomonas aeruginosa*. Furthermore, the compounds can be used for the treatment of pulmonary infections caused by *Burkholderia cepacia* (preferably in immunocompromized and cystic fibrosis patients), gastroenteritis and wound infections caused by *Aeromonas hydrophila*, sepsis in tropical and subtropical areas caused by *Chromobacterium violaceum*, diarrhoea with blood and haemolytic uremic syndrome (HUS) caused by *Escherichia coli*, yersiniosis triggered by *Yersinia enterocolitica* and *Y. pseudotuberculosis*, and transfusion-related sepsis and fistulous pyoderma caused by *Serratia liquefaciens*.

In a second embodiment the compounds can be used in the treatment of immunological diseases, particularly autoimmune diseases such as psoriasis, rheumatoid arthritis, multiple sclerosis and type 1 (autoimmune) diabetes, of cardiovascular diseases such as cardiac tachyarrhythmias, ischaemic heart disease, congestive heart failure, of allergic diseases and of diseases including cancer, breast cancer, obesity, lipid metabolism disorders, immune disease, immune deficiency or immune disorders.

In a third embodiment, the compounds can be used to prevent and/or treat plant diseases, where inhibition of the HSL-mediated signaling system reduces or abolishes virulence of bacterial plant pathogens. Such diseases include crown gall tumors caused by *Agrobacterium tumefaciens*, soft rot caused by *Burkholderia cepacia*, *Erwinia carotovora* and *Erwinia chrysanthemi*, sweet corn and maize infections caused by *Pantoea stewartii* and wilt disease caused by *Ralstonia solanacearum*.

In a fourth embodiment, the compounds can be used for the prevention and/or treatment of animal diseases, preferably fish diseases such as septicemia caused by *Aeromonas hydrophila* and *Vibrio anguillarum*, furunculosis in salmonids caused by *Aeromonas salmonicida*, prawn infections caused by *Vibrio harveyi* and enteric redmouth disease caused by *Yersinia ruckeri*, but also for the prevention and/or treatment of insect diseases caused, for example, by *Xenorhabdus nematophilus*.

In general, the present invention provides a method for reducing the virulence of bacterial pathogens employing an HSL-based signaling system. In a preferred form, a method is provided to remove, diminish, detach or disperse a bacterial biofilm from a living or nonliving surface by treating the surface with a compound of Formula (XIII), (I), (X), (XI) or (XII). This method is also useful to prevent biofilm formation on a living or nonliving surface by treating the surface with a compound of Formula (XIII), (I), (X), (XI) or (XII) before bacterial colonization can initialize. The term “biofilm” refers to cell aggregations comprising either a single type of organism or a mixture of more than one organism, then also referred to as “mixed biofilms”. It is clear to persons skilled in the art, that the compounds of the present invention can be applied in a wide variety of different fields such as environmental, industrial and medical applications in order to prevent and/or treat damages or diseases caused by bacteria.

In one aspect, the compounds of Formula (XIII), (I), (X), (XI) or (XII) can be used for all kinds of surfaces in private and public areas, where it is beneficial to inhibit quorum sensing systems of Gram-negative bacteria in order to prevent and/or treat colonization and biofilm formation. The compounds here can be used in form of a solution, powder or as a coating. The compound is preferably applied to the surface as a solution of the compound, alone or together with other materials such as conventional surfactants, preferably sodium dodecyl sulfate, or detergents, biocides, fungicides, antibiotics, pH regulators, perfumes, dyes or colorants, In combination with a bacteriocidal agent, e.g., the compounds of Formula (XIII), (I), (X), (XI) or (XII) inhibit virulence or biofilm formation whilst the bacteriocidal agent kills the pathogens.

In one embodiment, the compounds can be used as antibacterial agent for topical use in cleaning and treatment solutions such as disinfectants, detergents, household cleaner and

washing powder formulations in the form of a spray or a dispensable liquid. In a preferred form, these solutions can be applied to windows, floors, clothes, kitchen and bathroom surfaces and other surfaces in the area of food preparation and personal hygiene. In addition, the compounds of Formula (XIII), (I), (X), (XI) or (XII) can be used as antibacterial ingredients in personal hygiene articles, toiletries and cosmetics such as dentifrices, mouthwashes, soaps, shampoos, shower gels, ointments, creams, lotions, deodorants and disinfectants and storage solutions for contact lenses. In the case of contact lenses the compounds of Formula (XIII), (I), (X), (XI) or (XII) can also be applied as coating or additive to the lens material.

In another embodiment, the compounds can be used to prevent or treat bacterial biofilms in industrial settings such as ship hulls, paper and metal manufacturing, oil recovery, food processing and other applications where process disturbances are referred to biofouling on surfaces. The compounds here can be used in form of a solution, paint or coating, for example as an ingredient in cooling lubricants. The compounds can also be applied to water processing plants or drinking water distribution systems where the colonized surface (preferably by *Pseudomonas aeruginosa*) is preferably the inside of an aqueous liquid system such as water pipes, water injection jets, heat exchangers and cooling towers. Until now biocides are the preferred tools to encounter these problems, but since biocides do not have a high specificity for bacteria, they are often toxic to humans as well. This can be circumvented by the application of the compounds of the present invention.

In a further embodiment, the present invention relates to a method of inhibiting and/or preventing medical device-associated bacterial infections. The invention provides articles coated and/or impregnated with a compound of Formula (XIII), (I), (X), (XI) or (XII) in order to inhibit and/or prevent biofilm formation thereon. The articles are preferably surgical instruments, blood bag systems or medical devices; more preferably either permanently implanted devices such as artificial heart valve, prosthetic joint, voice prosthesis, stent, shunt or not permanently implanted devices such as endotracheal or gastrointestinal tube, pacemaker, surgical pin or indwelling catheter.

In a more preferred form, the indwelling catheters are urinary catheters, vascular catheters, peritoneal dialysis catheter, central venous catheters and needleless connectors. The catheter materials can be polyvinylchloride, polyethylene, latex, teflon or similar polymeric

materials, but preferably polyurethane and silicone or a mixture thereof. In order to reduce the risk of catheter-related bacterial infections, several catheters coated and/or impregnated with antiseptic or antimicrobial agents such as chlorhexidine/silver-sulfadiazine and minocycline/rifampin, respectively, have been developed. Furthermore, collection bags or layers sandwiched between an external surface sheath and a luminal silicone sheath have been constructed to overcome rapid loss of antimicrobial activity. Nevertheless, the emerging risk of bacterial resistance against traditional antibiotics limits the routine use of antibiotic-coated catheters.

the compounds of the present invention, however, offer the possibility to effectively reduce catheter-related bacterial infections with a low risk of resistance development due to a novel therapeutic strategy targeting highly sensitive signal transduction mechanisms in bacteria. The preferred form of application is the coating and/or impregnating of catheter materials on both the inner and outer catheter surfaces. More preferably, the compounds of Formula (XIII), (I) can be included in a mixture of antibacterial agents released continuously from a catheter-associated depot into the environment.

In a further embodiment, the compounds of the present invention and their pharmacologically acceptable salts can be administered directly to animals, preferably to mammals, and in particular to humans as antibiotics per se, as mixtures with one another or in the form of pharmaceutical preparations which allow enteral or parenteral use and which as active constituent contain an effective dose of at least one compound of the Formula (XIII), (I), (X), (XI) or (XII) or a salt thereof, in addition to customary pharmaceutical excipients and additives. The compounds of Formula (XIII), (I), (X), (XI) or (XII) can also be administered in form of their salts, which are obtainable by reacting the respective compounds with physiologically acceptable acids and bases.

The therapeutics can be administered orally, e.g., in the form of pills, tablets, coated tablets, sugar coated tablets, lozenges, hard and soft gelatin capsules, solutions, syrups, emulsions or suspensions or as aerosol mixtures. Administration, however, can also be carried out rectally, e.g., in the form of suppositories, or parenterally, e.g., in the form of injections or infusions, or percutaneously, e.g., in the form of ointments, creams or tinctures.

In addition to the active compounds of Formula (XIII), (I), (X), (XI) or (XII), the pharmaceutical composition can contain further customary, usually inert carrier materials or excipients. Thus, the pharmaceutical preparations can also contain additives or adjuvants commonly used in galenic formulations, such as, e.g., fillers, extenders, disintegrants, binders, glidants, wetting agents, stabilizers, emulsifiers, preservatives, sweetening agents, colorants, flavorings or aromatizers, buffer substances, and furthermore solvents or solubilizers or agents for achieving a depot effect, as well as salts for modifying the osmotic pressure, coating agents or antioxidants. They can also contain two or more compounds of the Formula (I) or (XIII) or their pharmacologically acceptable salts and also other therapeutically active substances.

Thus, the compounds of the present invention can be used alone, in combination with other compounds of this invention or in combination with other active compounds, for example with active ingredients already known for the treatment of the afore mentioned diseases, whereby in the latter case a favorable additive effect is noticed. Suitable amounts to be administered to mammalian in particular humans range from 5 to 1000 mg,

To prepare the pharmaceutical preparations, pharmaceutically inert inorganic or organic excipients can be used. To prepare pills, tablets, coated tablets and hard gelatin capsules, e.g., lactose, corn starch or derivatives thereof, talc, stearic acid or its salts, etc. can be used. Excipients for soft gelatin capsules and suppositories are, e.g., fats, waxes, semi-solid and liquid polyols, natural or hardened oils etc. Suitable excipients for the production of solutions and syrups are, e.g., water, alcohol, sucrose, invert sugar, glucose, polyols etc. Suitable excipients for the production of injection solutions are, e.g., water, alcohol, glycerol, polyols or vegetable oils.

The dose can vary within wide limits and is to be suited to the individual conditions in each individual case. For the above uses the appropriate dosage will vary depending on the mode of administration, the particular condition to be treated and the effect desired. In general, however, satisfactory results are achieved at dosage rates of about 0,1 to 100 mg/kg animal body weight preferably 1 to 50 mg/kg. Suitable dosage rates for larger mammals, e.g., humans, are of the order of from about 10 mg to 3 g/day, conveniently administered once, in divided doses 2 to 4 times a day, or in sustained release form.

In general, a daily dose of approximately 0,1 mg to 5000 mg, preferably 10 to 500 mg, per mammalian in particular human individual is appropriate in the case of the oral administration which is the preferred form of administration according to the invention. In the case of other administration forms too, the daily dose is in similar ranges. The compounds of Formula (I) or (XIII) can also be used in the form of a precursor (prodrug) or a suitably modified form, that releases the active compound in vivo.

In a further embodiment, the compounds of the present invention can be used as pharmacologically active components or ingredients of medical devices, instruments and articles with an effective dose of at least one compound of the Formula (XIII), (I), (X), (XI) or (XII) or a salt thereof. The amount of the compounds used to coat for example medical device surfaces varies to some extent with the coating method and the application field. In general, however, the concentration range from about 0,01 mg per cm² to about 100 mg per cm². In a similar way the amount of the compounds has to be adjusted to the application mode if the compounds of the invention are used as components or ingredients in cleaning or treatment solutions. In general, effective dosages range from about 0,1 μ M to about 1000 mM.

The following section shows examples for the synthesis of the compounds of the present invention and demonstrate their quorum sensing inhibiting effect.

Synthesis Method A (1,2-diacylhydrazine or 1-acyl-2-sulfonylhydrazine Derivatives) A solution of (1.2 eq) acid chloride or (1.2 eq) sulfonyl chloride in tetrahydrofuran was added to a solution of (1 eq) hydrazide in tetrahydrofuran and molecular sieve (0.4 nm) at 0°C. The mixture was stirred at room temperature. After 1 h the reaction mixture was concentrated in vacuum, and the resulting solid was purified by preparative thin layer chromatography (Merck, 20x20 cm, Silica gel 60 F₂₅₄, 1 mm) (CH₂Cl₂:MeOH, 100:1).

Synthesis Method B (1,2-diacylhydrazine or 1-acyl-2-sulfonylhydrazine Derivatives)

A solution of (1.2 eq) acid chloride or (1.2 eq) sulfonyl chloride in dimethylformamide was added to a solution of (1 eq) hydrazide in dimethylformamide and (1.2 eq) triethylamine at 0°C. The mixture was stirred at room temperature. After 1 h the reaction mixture was concentrated in vacuum, and the resulting solid was purified by preparative thin layer chromatography (Merck, 20x20 cm, Silica gel 60 F₂₅₄, 1 mm) (CH₂Cl₂:MeOH, 100:1).

Synthesis Method C (1,2diacylhydrazine or 1-acyl-2-sulfonylhydrazine Derivatives)

A solution of (1.2 eq) acid chloride or (1.2 eq) sulfonyl chloride in dichloromethane was added to a solution of (1 eq) hydrazide in dichloromethane and (1.2 eq) triethylamine at 0°C. The mixture was stirred at room temperature. After 1 h the reaction mixture was concentrated in vacuum, and the resulting solid was purified by preparative thin layer chromatography (Merck, 20x20 cm, Silica gel 60 F₂₅₄, 1 mm) (n-hexane:EtOAc, 9:1).

Synthesis Method D (Amide Derivatives)

A solution of (1.2 eq) acid chloride in tetrahydrofuran was added to a solution of (1 eq) amine in tetrahydrofuran and molecular sieve (0.4 nm) at 0°C. The mixture was stirred at room temperature. After 1 h the reaction mixture was concentrated in vacuum, and the resulting solid was purified by preparative thin layer chromatography (Merck, 20x20 cm, Silica gel 60 F₂₅₄, 1 mm) (CH₂Cl₂:MeOH, 100:1).

Synthesis Method E (Amide Derivatives)

A solution of (1.2 eq) acid chloride in dichloromethane was added to a solution of (1 eq) amine in dichloromethane and (1.2 eq) triethylamine at 0°C. The mixture was stirred at room temperature. After 1 h the reaction mixture was concentrated in vacuum, and the resulting solid was purified by preparative thin layer chromatography (Merck, 20x20 cm, Silica gel 60 F₂₅₄, 1 mm) (n-hexane:EtOAc, 9:1).

Synthesis Method F (Semicarbazide or Thiosemicarbazide Derivatives)

A solution of (1.3 eq) isocyanate or (1.3 eq) isothiocyanate in tetrahydrofuran was added to a solution of (1 eq) hydrazide in tetrahydrofuran and molecular sieve (0.4 nm) at 0°C. The

mixture was stirred at room temperature. After 1 h the reaction mixture was concentrated in vacuum, and the resulting solid was purified by preparative thin layer chromatography (Merck, 20x20 cm, Silica gel 60 F₂₅₄, 1 mm) (CH₂Cl₂:MeOH, 100:5).

Synthesis Method G (Hydrazide Derivatives)

A solution of (1.2 eq) acid chloride in tetrahydrofuran was added to a solution of (1 eq) hydrazine in tetrahydrofuran and molecular sieve (0.4 nm) at 0°C. The mixture was stirred at room temperature. After 1 h the reaction mixture was concentrated in vacuum, and the resulting solid was purified by preparative thin layer chromatography (Merck, 20x20 cm, Silica gel 60 F₂₅₄, 1 mm) (CH₂Cl₂:MeOH, 100:1).

Synthesis Method H (β -Ketoamides)

The acyl Meldrum's acid (1.2 eq) was dissolved in anhydrous benzene (concentration approximately 0.4 mol/l), and the amine (1.0 eq) was added. In case of amine hydrochlorides, one equivalent of triethylamine or N,N-diisopropylethylamine was added. The mixture was refluxed until tic showed complete conversion (typically, 4 to 6 h). The benzene solutions were directly chromatographed on silica gel in an appropriate solvent mixture (isohexane—ethyl acetate, dichloromethane—methanol, or dichloromethane—acetonitrile mixtures). Yields of the purified products typically were in the range from 30 to 75%.

In the following Table 2, the synthesis method employed in each case for the respective compound or whether the compound was obtained is indicated. Furthermore, the mass found by LC/(+)-ESI and LC/(-)-ESI mass spectrometry, the molecular mass, the NMR data (300.13 MHz, residual solvent peaks were used as internal standards (chloroform, δ 7.26; methanol, δ 3.31; dimethyl sulfoxide, δ 2.49; abbreviations: ψ =pseudo, br.=broad, s=singulet, d=doublet, t=triplet, q=quartet, quint.=quintet, sext.=sextet, m_c=multiplet centered, m=multiplet, CH_{ar}=aromatic H, J=¹H-¹H coupling constant) and the IC₅₀ range as a measure of anti-quorum sensing activity are indicated. The NMR data of the small signals due to enol-tautomers or possible rotamers of the 3-oxo-carboxylic acid amides are not listed.

2. Biosensor Assay

Quorum sensing inhibition of the compounds was investigated with the aid of the bioluminescent sensor strain *Escherichia coli* MT102 (pSB403) (Winson et al., *FEMS Microbiol. Lett.* 163:185-92, 1998). Plasmid pSB403 contains the *Photobacterium fischeri luxR* gene together with the *tuxI* promoter region as a transcriptional fusion to the bioluminescence genes *luxCDABE* of *Photobacterium luminescence*. Although *E. coli* pSB403 exhibits the highest sensitivity for the *Photobacterium fischeri* quorum sensing signal N-(3-oxohexanoyl)homoserine lactone (3-oxo-C6-HSL), a wide range of other HSL molecules are detected by the sensor (Winson et al., *FEMS Microbiol. Lett.* 163:185-92, 1998; Geisenberger et al., *FEMS Microbiol. Lett.* 184:273-8, 2000).

Inhibitory studies were conducted in a microtitre dish assay as follows: the *E. coli* sensor strain grown over night in LB medium (Sambrook et al., *Molecular Cloning: A Laboratory Manual*, 2nd Edn. Cold Spring Harbor Laboratory, New York, 1989) was diluted 1:4 and grown for another 1 hour at 30° C. After addition of 3oxo-C6-HSL (final concentration 100 nM) 100 μ l of an exponential culture suspension were filled in the wells of a FluoroNunc Polysorp microtitre dish. The test compounds were added to the culture in different concentrations and bioluminescence was measured after 4 hours of incubation at 30° C. with a Lamda Fluoro 320 Plus reader (Bio-Tek Instruments). Inhibitor-mediated reduction of light emission was correlated with the value obtained without addition of the test compounds. IC₅₀ values (concentration of inhibitor required for 50% inhibition of the signal compared to the signal without inhibitor) were determined by using a fitting function after drawing a graph of the activities of eight different inhibitor concentrations. The determined IC₅₀ range of each compound is listed in Table 2.

To exclude the possibility that the inhibitory effect is attributed to growth inhibition but not to a specific interaction of the test compound with the sensors quorum sensing system growth curves in the presence and absence of the test compounds were compared. *E. coli* MT102 (pSB403) was grown in LB medium at 37° C. in the presence of 0,4 mM test compound. Growth was measured as optical density at 600 nm. None of the compounds listed in Table 2 exhibit any growth inhibitory effects on the sensor strain *E. coli* MT102 (pSB403). **FIG. 2** shows the growth curves of representative compounds indicating a specific inhibitory effect of the compounds on the quorum sensing system.

3. Inhibition of protease production

The inhibitory effect of the compounds on quorum sensing regulated virulence factors was demonstrated by investigating the expression of extracellular proteases by *Pseudomonas aeruginosa*. The *P. aeruginosa* mutant strain PAO-JP2 (Pearson et al., *J. Bacteriol.* 179:5756-67, 1997) carrying mutations in the quorum sensing genes *lasI* and *rhlI* is unable to produce extracellular proteolytic enzymes. Protease expression can be completely restored by external addition of 3-oxo-C12-HSL. The protease assay was performed according to Riedel et al. (*J. Bacteriol.* 183:1805-9, 2001) with few modifications. PAO-JP2 was grown in LB medium at 30° C. and shaking at 250 rpm to an OD_{600nm} of 0.5. The test compounds were added at a final concentration of 0.4 mM and the culture was incubated for further 30 min at 30° C. and shaking at 250 rpm. After addition of 3-oxo-C12-HSL at a final concentration of 0.3 μ M the cultures were grown for an additional 6 hours at 30° C. and shaking at 250 rpm. The proteolytic activity was measured as described by Ayora & Götz (*Mol. Gen. Genet.* 242:421-30, 1994). 50 μ l culture supernatant were incubated with Azocasein (250 μ l 2%, Sigma, St. Louis, Mo.) for 1 hour at 37° C. After precipitation of undigested substrate with trichloroacetic acid (1.2 ml 10%) for 20 minutes at room temperature, followed by 5 minutes centrifugation at 13000 rpm, NaOH (0.75 ml 1M) was added to the supernatant. The relative protease activity was measured as absorbance at 440 nm (OD_{440nm}) of the supernatant divided by the optical density of the culture (OD_{600nm}). **FIG. 3** demonstrates the inhibitory effect of several compounds on protease production of *P. aeruginosa* PAO-JP2. The data presented are representative for at least three separate experiments.

To demonstrate that inhibition of protease production is due to a specific interference with the quorum sensing system growth curves in the presence and absence of the test compounds were compared. *P. aeruginosa* PAO-JP2 was grown in LB medium at 30° C. in the presence of 0.4 mM test compound. Growth was measured as optical density at 600 nm. None of the compounds listed in Table 2 exhibit any growth inhibitory effects on *P. aeruginosa* PAO-JP2. **FIG. 4** shows the growth curves of representative compounds indicating a specific inhibitory effect of the compounds on the quorum sensing system.

4. Inhibition of Biofilm Formation

The bacterial biofilm formation assay was performed in polystyrene microtitre dishes (FluoroNunc Polysorp) according to the method described by O'Toole & Kolter (*Mol. Microbiol.* 28:449-61, 1998) and Pratt & Kolter (*Mol. Microbiol.* 4 30:285-93, 1998) with few modifications (Huber et al., *Microbiology*, 147:2517-28, 2001). Cells were grown in the wells of the microtitre dishes in 100 μ l AB medium (Clark & Maaloe, *J. Mol. Biol.* 23:99-112, 1967) supplemented with 10 mM sodium citrate (Sigma). After addition of the test compound (0.4 mM) the cells were incubated for 48 hours at 30° C. The medium was then removed and 100 μ l of a 1% (w/v) aqueous solution of crystal violet (Merck) was added. Following staining at room temperature for 20 minutes, the dye was removed and the wells were washed thoroughly with water. For quantification of attached cells, the crystal violet was solubilized in a 80;20 (v/v) mixture of ethanol and acetone and the absorbance was determined at 570 nm (Ultrospec Plus spectrometer, Pharmacia). **FIGS. 5A and 5B** demonstrate the inhibitory effect of several compounds on biofilm formation of *Burkholderia cepacia* H11 (Römling et al., *J. Infect. Dis.* 170:1616-21, 1994; Gotschlich et al., *Syst. Appl. Microbiol.* 24:1-14, 2001). The data presented are representative for at least five separate experiments.

To exclude the possibility that biofilm inhibition is attributed to growth inhibition growth curves in the presence and absence of the test compounds were compared. *Burkholderia cepacia* H111 was grown in LB medium at 37° C. in the presence of 0.4 mM test compound. Growth was measured as optical density at 600 nm. None of the compounds listed in Table 2 exhibit any growth inhibitory effects on the sensor strain *Burkholderia cepacia* H111. **FIG. 6** shows the growth curves of the tested compounds indicating a specific inhibitory effect of the compounds on the quorum sensing system.
